

Low-Power CAN FD Bus Transceiver with Wake-Up and Fault Protection

FEATURES

- Compatible with the ISO 11898-2:2016 and SAE J2284-1 to SAE J2284-5 standard
- ➢ AEC-Q100 qualified
- Low power sleep mode and standby mode
- Remote wake-up function and local wake-up function
- ➢ ±58V BUS protection
- > ±30V receiver common mode input voltage
- SIT1043Q support 3.3V/5V MCU, and SIT1043Q/1 also support 1.8V MCU
- Driver (TXD) dominant timeout function
- > Undervoltage protection on VBAT, VCC and VIO pins
- High-speed CAN, support 5Mbps CAN with Flexible Data-Rate
- > Sleep mode INH output pin with power disable function
- -40°C to 150°C junction temperature range with overtemperature protection
- The typical loop delay from TXD to RXD is less than 100ns
- High Electro-Magnetic Immunity
- > Transceiver in unpowered state disengages from the bus
- With SPLIT pin for common-mode stabilization in SIT1043QT and SIT1043QTK version
- ➢ Available in SOP14 and DFN4.5×3-14 packages

DESCRIPTION

SIT1043Q is an interface chip applied between CAN protocol controller and physical bus, supports 5Mbps Flexible Data-Rate, and has the capability of differential signal transmission between bus and CAN protocol controller. The SIT1043Q features a CAN bus fault protection from -58V to +58V, and the receiver common mode input voltage can reach -30V to +30V, which is suitable for 12V or 24V application systems. The SIT1043Q is powered by multiple power supplies and has multiple system protection and diagnostic functions to improve the stability of the device and CAN. In addition, SIT1043Q has five working modes: normal mode, silent mode, standby mode, go-to-sleep mode and sleep mode. It supports local wake-up and remote wake-up in low power mode. The provided low power mode management can greatly save the power of CAN bus application system.

Applications: Automotive and Transport

PIN CONFIGURATION

PIN DESCRIPTION

芯力特

SiJ

PIN	SYMBOL	DESCRIPTION
1	TXD	Transmit data input.
2	GND	Ground.
3	VCC	5V bus power supply.
4	RXD	Receive data output; reads out data from the bus lines.
5	VIO	I/O port power supply.
6	EN	Enable control input.
7	INH	Used to control the working state of the external voltage regulator, set to high after a wake-up event.
8	ERRN	Error indication output.
9	WAKE	Local wake-up input.
10	VBAT	Battery power supply.
11	SPLIT	Common-mode stabilization output (Not connect in SIT1043Q/1 version).
12	CANL	Low-level CAN bus input and output.
13	CANH	High-level CAN bus input and output.
14	STBN	Standby mode control input.

INTERNAL CIRCUIT BLOCK DIAGRAM

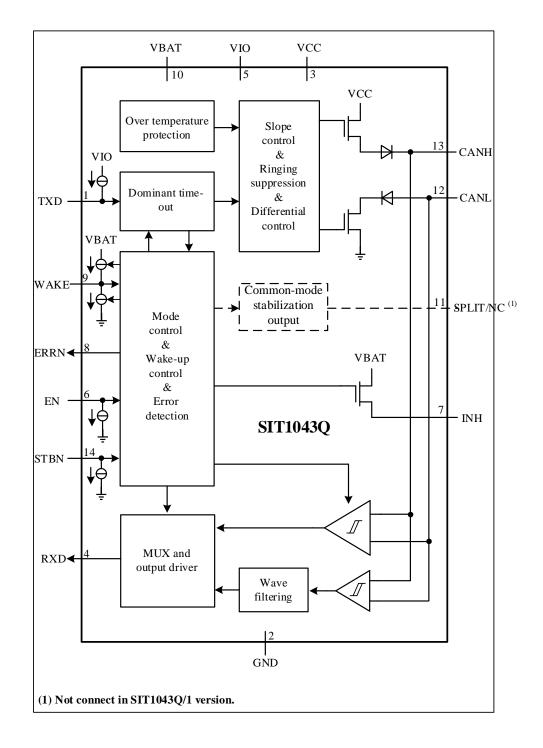

Fig 1 SIT1043Q block diagram

RECOMMENDED WORK STATUS

PARAMETER	SYMBOL	VALUE	UNIT
VBAT supply voltage	VBAT	4.5~40	V
VCC supply voltage	VCC	4.5~5.5	V
VIO supply voltage	VIO	2.8~5.5	V
VIO supply voltage (SIT1043Q/1)	VIO	1.7~5.5	V
Logic output pin high level output current (RXD&ERRN)	Ioh(logic)	>-2	mA
Logic output pin low level output current (RXD&ERRN)	Iol(logic)	<2	mA
INH output current	I _{O(INH)}	<1	mA
Ambient temperature	T _{amb}	-40~125	°C

LIMITING VALUES

PARAMETER	SYMBOL	VALUE	UNIT
Battery power supply	VBAT	-0.3~+58	V
Battery power supply (SIT1043Q/1)	VBAT	-0.3~+45V	V
Bus supply voltage	VCC	-0.3~+6	V
MCU side port	TXD, RXD, EN, STBN, VIO, ERRN	-0.3~+6	V
Bus side input voltage	CANH, CANL, SPLIT	-58~+58	V
Bus differential breakdown voltage	$V_{(CANH-CANL)}$	-20~+20	V
Storage temperature	T _{stg}	-55~150	°C
Virtual junction temperature	Tj	-40~150	°C

The maximum limit parameters mean that exceeding these values may cause irreversible damage to the device. Under these conditions, it is not conducive to the normal operation of the device. The continuous operation of the device at the maximum allowable rating may affect the reliability of the device. The reference point for all voltages is ground.

MODE TRANSITIONS

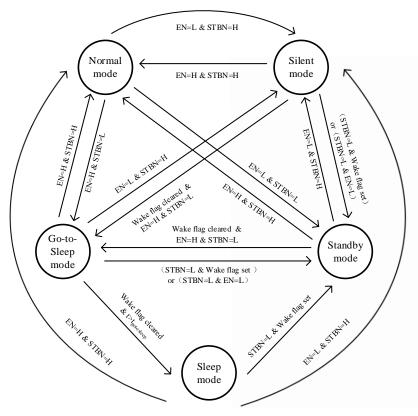

Fig 2 Mode transitions

Note: Valid VCC, VIO and VBAT voltages are present.

SIT1043Q Low-Power CAN FD Bus Transceiver with Wake-Up and Fault Protection

OPERATING MODE

Normal mode

The power supply is valid, both EN and STBN are set to high level, the device will enter the normal mode. In normal mode, the driver and high-speed receiver are enabled, the driver converts the digital input signal on the TXD to the bus analog level, while the receiver monitors the bus level and reacts it to the RXD. INH will be pulled high in normal mode.

Silent mode

The power supply is valid, setting EN to low level and STBN to high level, the device enters silent mode. The silent mode may also be referred to as a listen-only mode or a receive-only mode. In this mode, the driver is disabled, the high-speed receiver is enabled, the dominant and recessive signals of CANH and CANL are reflected to the RXD through the receiver. The bus will be biased to 0.5VCC, and INH will be pulled high.

Standby mode

The power supply is valid, and both EN and STBN are set to low level, and the device enters standby mode. Standby mode is a low-power mode in which the driver and high-speed receiver are disabled, INH is pulled high, and the device can still detect local wake-up and remote wake-up events. In addition, VBAT undervoltage can also enter standby mode, but the device does not detect wake-up events.

Go-to-Sleep mode

The power supply is valid, EN is set high, and STBN is set low. When $t < t_{go-to-sleep}$, the device will enter goto-sleep mode. Go-to-sleep mode is a transition mode that jumps to sleep mode. The working state of the device is consistent with the standby mode, the driver and high-speed receiver are disabled, and INH is pulled high. When the time in this mode exceeds $t_{go-to-sleep}$, it switches to sleep mode, and INH will go to a high-impedance state.

Sleep mode

The power supply is valid, EN is set high, STBN is set low, when $t>t_{go-to-sleep}$ can enter sleep mode. Sleep mode is a working mode with the lowest power consumption. In sleep mode, the driver and high-speed receiver are disabled, and the output port INH is in a high-impedance state, which can instruct to turn off the external voltage regulator, and the VCC power supply of the transceiver and MCU will not be available. In this state, SIT1043Q maintains power supply through the battery pin VBAT, so as to ensure the monitoring work of local wake-up and remote wake-up. In addition, when the power supply VCC or VIO is under-voltage and the under-voltage duration is longer than t_{DETUVD} (or floating), the device will also enter sleep mode, INH is in a high-impedance state, and a local wake-up or remote wake-up event can cause INH to be pulled high.

INTERNAL FLAG SIGNAL

FLAG	REASON FOR	EXTERNAL	FLAG SIGNAL CLEAR	NOTE
SIGNAL	APPEARING	INDICATION	FLAG SIGNAL CLEAK	NOIE
Power-on flag	VBAT power-on	Enter silent mode (from standby mode, Go-to-sleep mode, sleep mode) ERRN=L	Enter normal mode	
Wake-up request flag	Remote wake-up, local wake-up, initial power-on	Enter standby mode, Go-to-sleep mode, sleep mode ERRN=RXD=L	Enter normal mode, VCC or VIO undervoltage	
Wake-up source flag ⁽¹⁾	Remote wake-up, local wake-up, initial power-on	Enter normal mode: ERRN=L indicates local wake-up, ERRN=H indicates remote wake-up	TXD transitions ⁽²⁾ in normal mode, leaving normal operating mode, VCC or VIO undervoltage	The establishment of the power-up flag sets the wake-up source flag
UVD _{NOM} undervoltage	VCC undervoltage	No external indication	VCC recovers, the wake-up request flag appears	
flag	VIO undervoltage	No external indication	VIO recovers, the wake-up request flag appears	
UVD _{VBAT} undervoltage flag	VBAT undervoltage	No external indication	VBAT recovers	
Bus short circuit flag	BUS shorted to either power supply or GND	Only in normal mode ERRN=L ⁽³⁾	Leave normal mode	If the short circuit time is less than 4 TXD dominant and recessive transitions will not be detected
Local error flag	TXD dominant timeout	When entering silent mode from normal mode ERRN=L	RXD=L&TXD=H; enter	Once a TXD dominant timeout occurs, the drive will be disabled
Local error flag	TXD shorted to RXD	When entering silent mode from normal mode ERRN=L	normal mode	A short circuit of TXD to RXD occurs, the driver will be disabled
Local error flag	Bus dominant timeout	When entering silent mode from normal mode ERRN=L	RXD=H; enter normal mode	A bus timeout occurred and the drive is still enabled

SIT1043Q Low-Power CAN FD Bus Transceiver with Wake-Up and Fault Protection										
FLAG SIGNAL	REASON FOR APPEARING	EXTERNAL INDICATION	FLAG SIGNAL CLEAR	NOTE						
Local error flag	Over temperature protection	When entering silent mode from normal mode ERRN=L	The junction temperature returns to normal and RXD=L&TXD=H; the junction temperature returns to normal and jumps back to normal operation mode	In the event of an overtemperature condition, the driver will be disabled						

(1) The wake-up source flag will only identify the first wake-up request signal;

- (2) There are 4 dominant-recessive transitions of TXD, and each dominant-recessive period of this transition is at least 4µs (only in SIT1043QT and SIT1043QTK version);
- (3) ERRN can indicate the bus short-circuit flag after 4 TXD dominant-recessive transitions (each dominant-recessive cycle last at least 4µs); (only in SIT1043QT and SIT1043QTK version)

The device carries out system diagnosis through the above series of flag signals and indicates the cause of the failure. The MCU can judge the internal working state of the system or the cause of the fault through some mode switching and the indication of the transceiver chip ERRN and RXD pins.

Power-on flag

The power-on flag refers specifically to the power-on event of the battery power supply VBAT. The power-on flag is set when VBAT returns to normal operating voltage from a voltage lower than $V_{UVDVBAT}$. Once the device enters silent mode from standby or sleep mode, ERRN is pulled low to indicate that the power-on flag is set. When entering normal operating mode, the power-on flag will be cleared. The power-on flag clears the UVD_{NOM} undervoltage flag and sets the wake-up request flag and wake-up source flag.

Wake-up request flag

SIT1043Q can realize low-power wake-up function in two ways: local wake-up and remote wake-up.

Local wake-up

SIT1043Q realizes the function of local wake-up through the WAKE port. In standby mode or sleep mode, as long as there is a valid rising or falling edge on the WAKE pin, it will be detected as a local wake-up event. A valid rising edge means that the voltage of the WAKE port jumps from a voltage lower than $V_{th(WAKE)}$ to a voltage higher than $V_{th(WAKE)}$, and the duration of this jump is longer than $t_{wake(local)}$, which can be considered as a valid rising edge, as shown in Figure 3; a valid falling edge is when the voltage at the WAKE port transitions from a voltage above $V_{th(WAKE)}$ to a voltage below $V_{th(WAKE)}$, and the duration of this transition is greater than $t_{wake(local)}$, which can be considered as a valid falling edge, as shown in Figure 4. Any transitions of duration less than $t_{wake(local)}$ and transitions that do not cross the threshold voltage $V_{th(WAKE)}$ will be filtered

out.

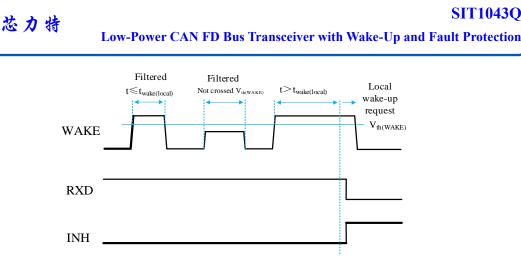

Fig 3 Local wake-up for WAKE rising edge

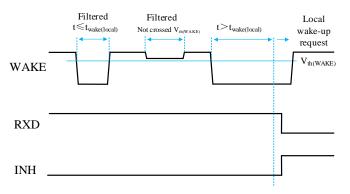

Fig 4 Local wake-up for WAKE falling edge

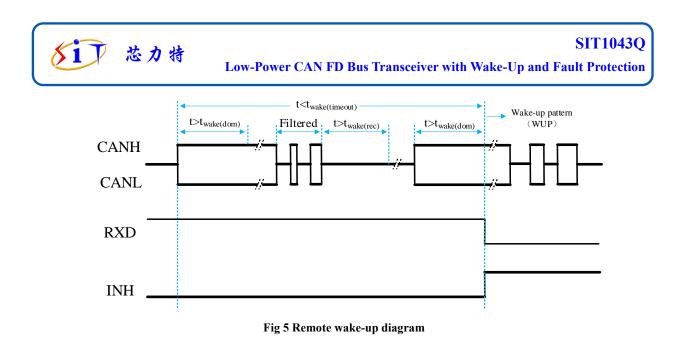

Remote wake-up

The SIT1043Q implements a remote wake-up function through a low-power receiver to inform the MCU that the bus has been activated and the node should resume normal operation. In sleep mode, when a valid remote wake-up pattern (WUP) appears, the device will wake up and jump to standby mode, RXD will be pulled low and INH will be pulled high.

According to ISO11898-2:2016, the complete WUP consists of: a filtered dominant level (duration greater than $t_{wake(dom)}$), a filtered recessive level (duration greater than $t_{wake(rec)}$) and another filtered dominant level flat (duration greater than $t_{wake(dom)}$). This dominant-recessive-dominant level signal must appear within $t_{wake(timeout)}$ time, otherwise the internal wake-up logic will be reset and restart the monitoring of the bus.

The RXD pin will remain high until the wake-up event is triggered. The above mentioned dominant and recessive levels will be ignored (filtered out) if the duration is lower than $t_{wake(busdom)}$ and $t_{wake(busrec)}$. A wake-up event will not be responded when any of the following events occurs while a valid wakeup pattern is received:

- (1) The device switches to the normal working mode;
- (2) The complete wake-up request frame is not received within the t_{wake(timeout)};
- (3) VCC or VIO undervoltage is detected (UVD_{NOM} flag signal is set).

Wake-up source flag

SIT1043Q can identify the wake-up source through the wake-up source flag, and the wake-up source flag can be represented by the level of the ERRN pin when the chip enters the normal mode. If the wake-up flag is generated by the local wake-up request given by the WAKE pin, the ERRN pin is low level after jumping to the normal operating mode. Conversely, if the ERRN pin is high, it can indicate the remote wake-up signal given by the CAN bus. In normal mode, after the TXD port transmits four explicit and implicit transitions, if a bus short-circuit flag is generated, the wake-up source flag will be overwritten. The chip leaving the normal operating mode also clears the wake-up source flag. This flag is also generated on initial power-on.

UVDNOM undervoltage flag

The SIT1043Q has an undervoltage detection function on the power supply VCC and VIO, which can set the UVD_{NOM} undervoltage flag and place the device in a protected state. When VCC is lower than its undervoltage threshold V_{UVDVCC} and the undervoltage time is greater than t_{DETUVD} or VIO is lower than its undervoltage threshold V_{UVDVIO} and the undervoltage time is greater than t_{DETUVD} , by setting the UVD_{NOM} undervoltage flag, the device will be forced to enter sleep mode and wake up locally and with remote wake-up are still normal. INH is high impedance and further instructs the external regulator to shut down, which saves unnecessary power consumption and avoids the bus from being disturbed. The UVD_{NOM} undervoltage flag is cleared when VCC is higher than V_{UVDVCC} and the recovery time is greater than t_{RECUVD} or VIO is higher than V_{UVDVIO} and the recovery time is greater than t_{DETUVD} . At the same time, the establishment of the wake-up request flag and the power-up flag and the low-to-high transition of STB will clear the UVD_{NOM} undervoltage flag.

UVD_{VBAT} undervoltage flag

The battery power VBAT of the SIT1043Q also has an undervoltage detection function. When VBAT is lower than $V_{UVDVBAT}$, the UVDV_{BAT} undervoltage flag is set, the device enters standby mode, and the transceiver will be disconnected from the bus (zero load). When the voltage at pin VBAT is restored, the UVDV_{BAT} undervoltage flag is cleared and the transceiver will switch to the operating mode indicated by the logic levels on the STBN and EN pins.

Bus short circuit flag

In normal mode, if the bus is shorted to VBAT, VCC or GND, and TXD appears for 4 consecutive dominant-recessive transitions (each dominant-recessive period is at least 4µs), the bus short-circuit flag will be set, the

establishment of the bus short flag is indicated by pulling ERRN low. A power cycle or the transceiver reenters normal operating mode to clear the bus short flag.

Local error flag

1

芯力特

SIT1043Q can detect four kinds of local error events: TXD dominant timeout, TXD and RXD short circuit, bus dominant timeout, over temperature protection. Whenever any of these events occur, a local error flag is generated, and when the device transitions from normal mode to silent mode, ERRN is pulled low, indicating that a local error flag has been set.

TXD dominant timeout

In normal mode, if a low level voltage on pin TXD lasts longer than the internal timer value $t_{dom(TXD)}$, the transmitter will be disabled, driving the bus into a recessive state. This prevents the bus line from being driven to a permanent dominant state (blocking all network traffic) due to a hardware or software application failure on pin TXD being forced permanently low.

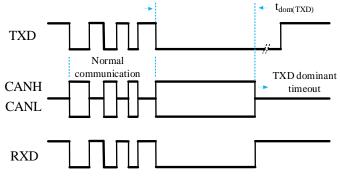

Fig 6 TXD dominant timeout diagram

TXD and RXD short circuit

SIT1043Q has the protection function of short circuit between TXD and RXD, which can avoid the periodic deadlock situation of the local device. In normal mode or silent mode, if a short circuit occurs between the TXD and RXD of the device, and the duration of the short circuit exceeds $t_{dom(TXD)}$, the device will consider that a short circuit between TXD and RXD has occurred, the local error flag is established, and the driver will be disabled.

Bus dominant timeout

When the bus is short-circuited, if the bus has a dominant level whose duration is greater than the internal timer value $t_{dom(BUS)}$, it will be regarded as a bus dominant timeout event and a local error flag will be established.

Over temperature protection

SIT1043Q has an over temperature protection function. If the junction temperature of the device exceeds the over temperature shutdown temperature $T_{j(sd)}$, the bus driver circuit will be shut down, thereby blocking the transmission path from TXD to the bus, so during thermal shutdown the level is biased in a recessive state while the rest of the chip remains functional. Because the driver tube is the main energy consuming component, turning off the driver tube can reduce the power consumption and thus reduce the chip temperature.

DC PARAMETERS

Tested under recommended operating conditions: VBAT=4.5V to 40V, VCC=4.5V to 5.5V, VIO=2.8V to 5.5V, T_j=-40°C to 150°C. Unless otherwise stated, all typical values are measured at T_{amb} =25°C, supply voltage VBAT=12V, VCC =5V, VIO=5V, R_L=60 Ω .

SOP14 DIMENSIONS

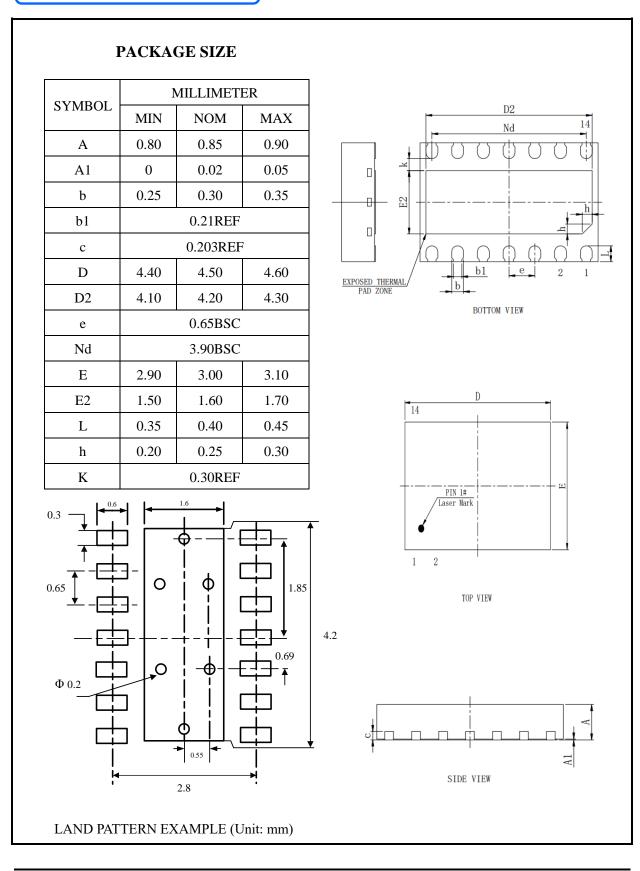

芯力特

8 i J

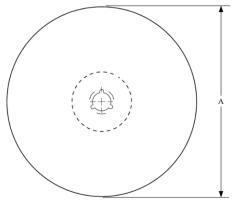

DFN4.5×3-14 DIMENSIONS

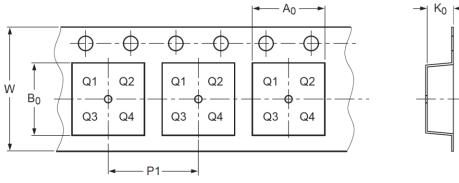

TAPE AND REEL INFORMATION

AO	Dimension designed to accommodate the
AU	component width
BO	Dimension designed to accommodate the
БО	component length
К0	Dimension designed to accommodate the
K0	component thickness
W	Overall width of the carrier tape
P1	Pitch between successive cavity centers

Direction of Feed

PIN1	is	in	quadrant	1	
------	----	----	----------	---	--

Package Type	Reel Diameter A (mm)	Tape Width W1 (mm)	A0 (mm)	B0 (mm)	K0 (mm)	P1 (mm)	W (mm)
SOP14	330±1	12.4	$6.50^{+0.20}_{-0.1}$	$9.30^{+0.20}_{-0.1}$	2.0±0.10	8.00±0.1	16.00±0.10
DFN4.5×3-14	329±1	12.4	3.75±0.1	4.25±0.1	1.00±0.1	8.00±0.1	12.00±0.3

ORDERING INFORMATION

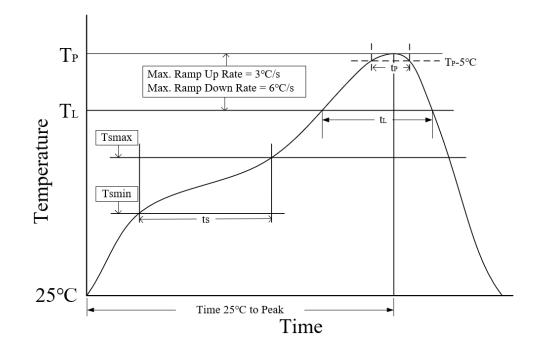

TYPE NUMBER	PACKAGE	PACKING
SIT1043QT	SOP14	Tape and reel
SIT1043QT/1	SOP14	Tape and reel
SIT1043QTK	DFN4.5×3-14	Tape and reel
SIT1043QTK/1	DFN4.5×3-14	Tape and reel

SOP14 is packed with 2500 pieces/disc in braided packaging; Leadless DFN4.5×3-14 is packed with 3000 pieces/disc in braided packaging.

Low-Power CAN FD Bus Transceiver with Wake-Up and Fault Protection

REFLOW SOLDERING

Parameter	Lead-free soldering conditions
Ave ramp up rate $(T_L \text{ to } T_P)$	3 °C/second max
Preheat time ts (T_{smin} =150 °C to T_{smax} =200 °C)	60-120 seconds
Melting time $t_L (T_L=217 \text{ °C})$	60-150 seconds
Peak temp T _P	260-265 °C
5 °C below peak temperature t_P	30 seconds
Ave cooling rate $(T_P \text{ to } T_L)$	6 °C/second max
Normal temperature 25°C to peak temperature TP time	8 minutes max

REVISION HISTORY

Version number	Data sheet status	Revision date
V1.0	Initial version	June 2022
V1.1	Modified the description of SPLIT port parameters; Added transceiver test circuit diagrams; Added tape information; Added reflow information.	August 2022
V1.2	Added ringing suppression in circuit block diagram; Modified the description of WAKE port parameters; Added test conditions for V _{TXsym} .	September 2022
V1.3	Updated the t _{wake(timeout)} minimum; Added "LAND PATTERN EXAMPLE".	December 2022
V1.4	Added AEC-Q100 qualified; Added the bus side input voltage range in SPLIT port; Updated typical application circuit.	April 2023
V1.5	Added "Compatible with the SAE J2284-1 to SAE J2284-5 standard"	April 2024
V1.6	Added a new ordering type number SIT1043Q/1.	August 2024
