

FEATURES

- ➤ Compatible with the ISO 11898-2:2024 and SAE J2284-1~ SAE J2284-5 standard
- ➤ AEC-Q100 qualified
- > Thermally protected
- ≥ ±42V BUS Protection
- > Transmit Data (TXD) dominant time-out function
- ➤ Low-power standby mode with wake-up function
- > SIT1044GQT/3 and SIT1044GQTK/3 I/O pins support 1.8V, 3.3V and 5V MCU
- Undervoltage protection on pins VCC and VIO
- > Timing guaranteed for data rates up to 5 Mbps in the CAN FD fast phase
- ➤ High ElectroMagnetic Immunity
- ➤ Unpowered state disengages from the bus
- Available in SOP8 and DFN3*3-8 packages. DFN3*3-8 with improved Automated Optical Inspection (AOI) capability.

DESCRIPTION

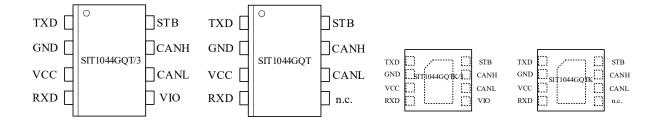

SIT1044GQ is an interface chip used between the CAN protocol controller and the physical bus. It can be used for in-vehicle, industrial control and other fields. It supports 5Mbps (CAN FD), and has the ability to perform differential signal transmission between bus and the CAN protocol controller.

SIT1044GQ is fully compatible with the SIT1044Q and other family products. SIT1044GQ features improved bus signal symmetry and lower electromagnetic radiation performance.

PARAMETER	SYMBOL	CONDITIONS	VALUE	UNIT
Bus supply voltage	VCC	4.5	5.5	V
MCU side port supply voltage	VIO	1.7	5.5	V
CANH/CANL input or output voltage	V_{can}	-42	+42	V
Bus differential voltage	$V_{ m diff}$	1.5	3.0	V
Virtual junction temperature	T_j	-40	150	°C

PIN CONFIGURATION

PIN DESCRIPTION

PIN	SYMBOL	DESCRIPTION	
1	TXD	transmit data input	
2	GND	ground	
3	VCC	supply voltage	
4	RXD	receive data output	
5	VIO	transceiver I/O level conversion power supply voltage (SIT1044GQT/3, SIT1044GQTK/3)	
3	n.c.	Not connected in SIT1044GQT and SIT1044GQTK version.	
6	CANL	LOW-level CAN-bus line	
7	CANH	HIGH-level CAN-bus line	
8	STB	standby mode control input, low level is high speed mode	

Note: The metal pad on the back of the DFN3*3-8 package is recommended to be grounded.

LIMITING VALUES

PARAMETER	SYMBOL	CONDITIONS	VALUE	UNIT
Supply voltage	VCC, VIO	pins VCC, VIO	-0.3~+7	V
MCU side port	$V_{TXD}, V_{RXD}, V_{STB}$	pins TXD, RXD, STB	-0.3~+7	V
Bus side input voltage	VCANL, VCANH	pins CANH, CANL	-42~+42	V
Bus differential breakdown voltage	V _{CANH-CANL}		-42~+42	V
		IEC 61000-4:2: pins CANH, CANL	-6~+6	kV
	$ m V_{ESD}$	HBM, AEC Q100-002		
ElectroStatic Discharge		All pins	-4~+4	kV
		Pins CANH and CANL	-8~+8	kV
		CDM, all pins	-2000~+2000	V
		Pulse	-100	V
To a start a Maria		Pulse 2a	75	V
Transient voltage	$ m V_{trt}$	Pulse 3a	-150	V
		Pulse 3b	100	V
Storage temperature	T _{stg}		-55~150	°C
Virtual junction temperature	Tj		-40~150	°C

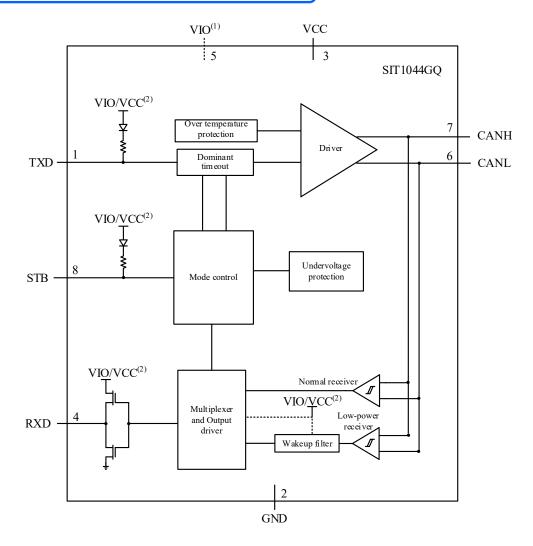

The maximum limit parameters mean that exceeding these values may cause irreversible damage to the device. Under these conditions, it is not conducive to the normal operation of the device. The continuous operation of the device at the maximum allowable rating may affect the reliability of the device. The reference point for all voltages is ground.

THERMAL CHARACTERISTICS

PARAMETER	SYMBOL	CONDITIONS	VALUE	UNIT

ADDITIONAL DESCRIPTION

1 Sketch

The SIT1044GQ is an interface chip designed for use between CAN protocol controllers and the physical bus, applicable in automotive and industrial control fields. It supports Flexible Data-Rate of up to 5Mbps and features differential signal transmission capability between the bus and the CAN protocol controller.

2 Overtemperature protection

The device is protected against overtemperature conditions. If the junction temperature exceeds the shutdown junction temperature, $T_{j(sd)}$, the CAN bus drivers are disabled. When the junction temperature drops below $T_{j(sd)rel}$, the CAN bus drivers recover once TXD has been reset to HIGH and Normal mode is selected (waiting for TXD to go HIGH prevents output driver oscillation due to small variations in temperature).

3 Undervoltage protection

If VCC drops below the standby undervoltage detection threshold $(V_{uvd(stb)(VCC)})$ for $t_{det(uv)}$, the transceiver switches to Standby mode. The logic state of pin STB is ignored until VCC has recovered.

In SIT1044GQT/3 and SIT1044GQTK/3 version, if VIO drops below the switch-off undervoltage detection threshold ($V_{uvd(swoff)(VIO)}$) for $t_{uvd(swoff)}$, the transceiver switches to Off mode and disengages from the bus (high-ohmic) until VIO has recovered.

In the SIT1044GQ, if VCC drops below the switch-off undervoltage detection threshold ($V_{uvd(swoff)(VCC)}$) for $t_{uvd(swoff)}$, the transceiver switches to Off mode and disengages from the bus (high-ohmic) until VCC has recovered.

4 Operating modes

SIT1044GQ supports three operating modes, Normal, Standby and Off. The operating mode is selected via pin STB. The following table shows the corresponding mode status.

Mode	Inputs		Outputs		
Mode	STB TXD CAN d		CAN driver	RXD	
		LOW	Dominant	LOW	
Normal	LOW	HIGH	Recessive	LOW when bus dominant	
	HIGH Reces		Recessive	HIGH when bus recessive	
Standby	HIGH	X	Diagod to ground	Follows BUS when wake- up detected	
Standby	піоп	Λ	Biased to ground	HIGH when no wake-up detected	
Off ⁽¹⁾	X	X	High-ohmic state	High-ohmic state	

⁽¹⁾ Off mode is entered when the voltage on pin VIO or pin VCC is below the switch-off undervoltage detection threshold.

4.1 Off mode

The SIT1044GQ switches to Off mode from any mode when the supply voltage falls below the switch-off undervoltage threshold $V_{uvd(swoff)}$. This is the default mode when powered on.

In Off mode, the pins CAN and RXD are in a high-ohmic state.

4.2 Standby mode

When the supply voltage rises above the switch-off undervoltage detection threshold, the SIT1044GQ starts to boot up, triggering an initialization procedure.

Standby mode is selected when pin STB goes HIGH. In this mode, the transceiver is unable to transmit or receive data and a low-power receiver is activated to monitor the bus for a wake-up pattern. The transmitter and Normal-mode receiver blocks are switched off and the bus pins are biased to ground to minimize system supply current. Pin RXD follows the bus after a wake-up request has been detected.

A transition to Normal mode is triggered when STB is forced LOW.

If the supply voltage is below the Standby undervoltage hysteresis voltage $V_{uvd(stb)}$ when STB goes LOW, the SIT1044GQ will remain in Standby mode.

Pending wake-up events will be cleared and differential data on the bus pins converted to digital data via the low-power receiver and output on pin RXD.

In SIT1044GQT/3 and SIT1044GQTK/3 version, the low-power receiver is supplied from VIO and can detect CAN bus activity when VIO is above switch-off undervoltage detection voltage $V_{uvd(swoff)}$ (even if VIO is the only available supply voltage).

4.3 Normal mode

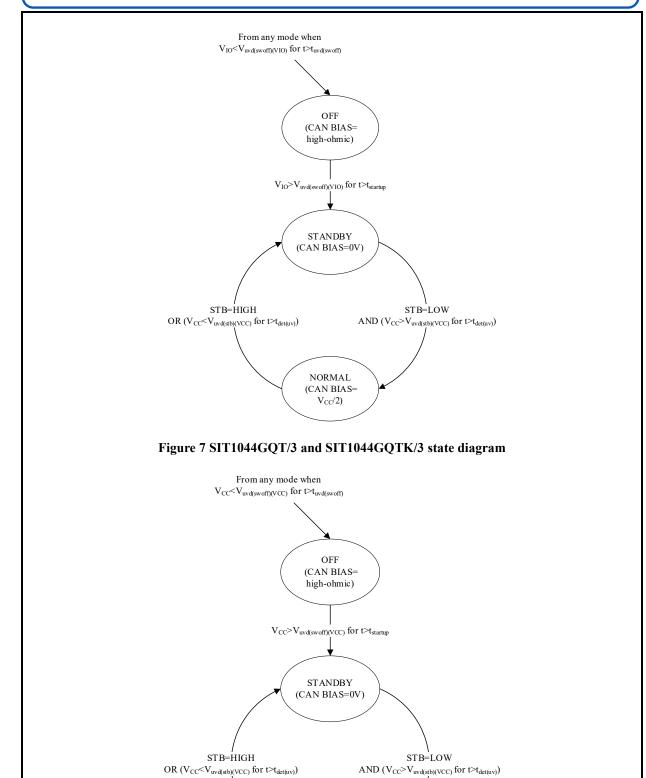

A LOW level on pin STB selects Normal mode, provided the supply voltage on pin VCC is above the standby undervoltage detection threshold, $V_{uvd(std)}$.

In this mode, the transceiver can transmit and receive data via bus lines CANH and CANL. Pin TXD must be HIGH at least once in Normal Mode before transmission can begin. The differential receiver converts the analog data on the bus lines into digital data on pin RXD. The slopes of the output signals on the bus lines into digital data on pin RXD. The slopes of the output signals on the bus lines are controlled internally and are optimized in a way that guarantees the lowest possible EME. In order to support high bit rates, especially in CAN FD systems, the Signal Improvement function largely eliminates topology-related reflections and impedance mismatches. In recessive state, the output voltage on the bus pins is VCC/2.

4.4 Operating modes and gap-free operation

Gap-free operation guarantees defined behavior at all voltage levels. Supply voltage-to-operating mode mapping is detailed in **Figure 9** in the state diagrams (**Figure 7** and **Figure 8**).

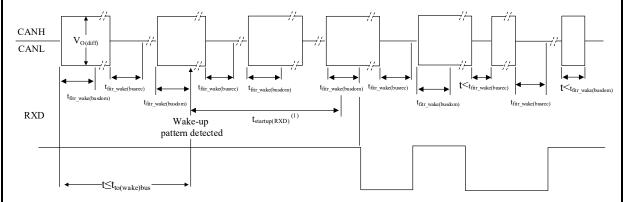

Figure 9 Supply voltage ranges and gap-free operation

5 Dominant timeout function

A "TXD dominant time-out" timer is started when pin TXD is set LOW. If the LOW state on this pin persists for longer than $t_{to(dom)TXD}$, the transmitter is disabled, releasing the bus lines to recessive state. This function prevents a hardware and/or software application failure from driving the bus lines to a permanent dominant state (blocking all network communications). The TXD dominant time-out timer is reset when pin TXD goes HIGH.

6 Remote wake-up

SIT1044GQ wakes up from Standby mode when dedicated wake-up pattern is detected on the bus. Wake-up timing is shown in the **Figure 10**.

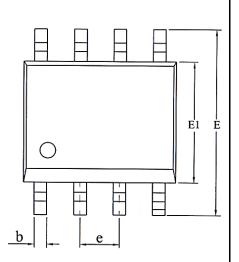

(1) During $t_{startup(RXD)}$, the low-power receiver is on but pin RXD is not active (i.e. HIGH/recessive). The first dominant pulse of width $\geq t_{filr}$ (wake)bus that ends after $t_{startup(RXD)}$ will trigger RXD to go LOW/dominant.

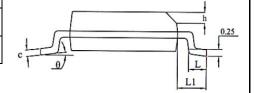

Figure 10 Wake-up timing
